#### Abstract

Multilayer Perceptron (MLP) models have been developed to predict two-phase average void fraction and probability density function (PDF) of void fraction in $90^{\circ}$ bends. The Artificial Neural Network (ANN) methodology was reported using MLP trained with 2 algorithms. Logarithmic sigmoid transfer function was used in a single hidden layer for both algorithms (Gradient descent (GDMV) and Levenberg-Marquardt (LM) algorithms). Both MLP models were optimised by varying the number of neurons in the hidden layer while monitoring the Mean Square Error (MSE). The performance of the models was evaluated using the Average Absolute Relative Error (AARE) and Cross Correlation Coefficient (R). Both MLP models developed for the prediction of average void faction before the bend performed excellently well. However, the MLP model trained with LM algorithm having 3 neurons in the hidden layer gave better performance. Similarly, the MLP model trained with LM algorithm, having 11 neurons in the hidden layer for the prediction of PDF of void fraction before the bend gave excellent prediction. Model performance for the MLP models after the bend gave poor generalisation property. However, the MLP model based on GDMV algorithm gave better prediction for predicting average void fraction and PDF of void fraction after the bend. It was concluded that MLP models may with some confidence be used to predict the average void fraction and the PDFs of void fraction observed before a vertical $90^{\circ}$ bend.

Keywords: $90^{\circ}$ bend, air-silicone oil; void fraction; MLP; ANN; LM algorithm; GDMV algorithm; modelling.

## 1. Introduction

Two phase gas-liquid flows are both common and important in oil and gas production and flow lines of different configurations [2]. Two-phase flows are often conveyed through pipes of various configurations as well as pipe fittings such as bends [27]. According to [3] the presence of bends introduces secondary flows, redistribution of multiphase fractions, flow excursions, deviation in flow paths etc. The orientation of the connecting pipe make a difference in the flow patterns for reasons which include sharp deviation in flow path around bends and also because of the role played by gravity and density difference between the two fluids. Two important characteristics of two-phase flows around bends are highly fluctuating voids immediately after bends and changes in flow pattern. It is therefore imperative to develop a means for predicting flow characteristics. A method that has been successfully used for determining flow pattern is the probability density function (PDF) of void fraction. A number of modelling techniques have been employed in the past for void fraction and flow pattern prediction. The models are either empirical, mechanistic of
numerical. However, the application of Multilayer Perceptron Modelling (MLP), for the prediction of flow characteristics around bends has received little attention in the peer review literature. Most of the investigations have been restricted to experimental investigation: [2], [11] - [14], [17], and [25] address the issue of gas-liquid systems but most of the reported experiments are not extended to the application of MLP to predict such flows in bends.

MLP modelling is a type of numerical modelling. Numerical modelling technique is a useful tool in visualising the dynamic behaviour of real systems. It has a unique advantage in that there is no limit to the complexity of problem it can solve [26]. MLP models are similar to ANN and are based on the concept of interconnected systems of simple-processing units [10].

### 1.1. The Back-propagation Algorithm

In back-propagation algorithms the processing elements are arranged in layers, signals are sent forward while errors are propagated backwards. The layers consist of input, hidden and outputs layers. The number of processing elements in the input layer is defined by the number of independent input variables, while that of the hidden layer is determined by method of optimisation. There may be one or more intermediate hidden layers as illustrated in Figure 1.

Figure 1: Schematic diagram of the ANN [24].
Generally MLP modelling similar to ANN use either supervised or unsupervised learning during the process of model training. The method used in back-propagation algorithm is supervised learning, which means that the user provides the algorithm with examples of the inputs and outputs for the network to compute, and then the error (difference between actual and expected results) is calculated. The concept of the back-propagation algorithm is to reduce this error, until the ANN learns the training data. The training usually begins with random weights (or user specified weights), and the goal is to adjust them so that the error will be minimal [10].

### 1.2. Two-phase flow in $90^{\circ}$ bends

A number of experimental and modelling studies have been carried out in the past for two phase gas-liquid flows in bends. Majority of these works were for air-water systems and very few used advanced instrumentation for their investigation. A Visual and experimental study for twophase flow through a transparent pipe $76-\mathrm{mm}$ diameter was carried out by [14]. Their flow facility consisted of a vertical $90^{\circ}$ bends of 305 and 610 mm radii of curvature. The investigation for limited to bubble and slug flow regimes for air-water flow. The goal was to interrogate the competitive effects of centrifugal and gravity forces on the ensuing flow distribution in bends. A 2D modelling study was carried out by [11] for flow around a vertical $90^{\circ}$ bends. Model predictions from their work were compared results of experimental investigation of [14]. The results showed poor correlation between model predictions and experimental measurements. An extension of the 2D model to a 3D model was carried out by [12] who obtained better model predictions for experimental measurements. [13] developed an improved 3-D numerical simulation, in which a substantially different solution algorithm, with an additional momentum term, was adopted. They applied the models to both air-water and gas-oil mixtures. The predicted simulation flow data gave better agreement with the experimental data compared to those obtained by the 2-D model in [11]. There was, however, a shortage of experimental data at the time for validation of their gas-oil
simulation. An experimental and numerical modelling study was carried out by [17] for air-water flow in a bend of 630 mm radius of curvature. The flow configuration was horizontal to vertical though the bend and the pipe were made of transparent acrylic material of internal diameter 100mm . Visual observations of the flow regime was done using a 200 Hz digital camera and an autoregressive modelling method. They observed two flow regimes (Slug and churn flow) in the riser and three flow regimes (stratified, slug and enhanced slug) in the horizontal pipe section. The time dependent behaviour of two-phase flow was modelled by an in-house code named Solution Package for Hyperbolic Functions (SOPHY-2). In most of the tested data an excellent agreement was found between the experimental and modelling results. [2] used electrical capacitance tomography (ECT), high speed video and wire mesh sensor (WMS) to interrogate the effects of $90^{\circ}$ bends on two-phase air-silicone oil flows. The downstream pipe was kept horizontally while the upstream pipe was vertical. The characteristic PDF of void fraction for various flow rates were used to identify the flow regime upstream and downstream of the bend. They observed bubble, stratified, slug and semiannular flows downstream of the vertical $90^{\circ}$ bend whiles the flow patterns exhibited upstream of the bend was the same as for the horizontal $90^{\circ}$ bend. [25] conducted an experimental study of the behaviour of two-phase air-water flow from the vertical to the horizontal through a $90^{\circ}$ bend using conductance probes technique. Void fraction measurement was done using the conductance probes (3 upstream and 6 downstream of the bend). The characteristic PDF of void fraction, power spectral density (PSD) of the time series of cross sectional average void fraction and visual observations were used to characterize the flow behaviour. For the horizontal pipe, plug, slug and stratified wavy flow patterns were seen while slug and churn flows in the vertical pipe.

### 1.3. Application of Artificial Neural Network (ANN) methodology to gas-liquid flows

[15] used ANN to process signals measured using a conductivity probe with the aim of classifying them into various flow patterns. They used visual map identification to validate the results of ANN model predictions. The ANN predictions were in good agreement with results of visual identification. A comparative model study was carried out by [21] for the prediction of pressure loss in five venture scrubbers. They compared the results of ANN prediction with a number of other models and concluded that predictions of the ANN models were better within the range of data tested. [30] used adopted inputs, all representing the characteristics of PSD, in training a three-layered feed forward ANN for the prediction of flow pattern. The model predictions gave good agreement to the observed flow patterns. A comparative study of CFD and ANN was carried out by [4]. They used both CFD and ANN for the prediction of pressure drop in two phase gasliquid flows in $2-\mathrm{cm}$ diameter, $6-\mathrm{m}$ long pipe. The inputs to their ANN model were gas velocity, liquid velocity and tube inclination. Predictions from both models indicated that the CFD model performed better. [19] used ANN technique in predicting the pressure drop observed in three phase flow conditions. The resilient back-propagation algorithm was used to formulate the ANN model. This method gave correlation coefficients up to $98.82 \%$. [9] employed ANNs in characterizing observed flow pattern. The method was based upon an analysis of the PSD determined from the differential pressures measured within a horizontal pipe conveying. Over the range of data tested, model predictions were in good agreement with experimental data. Three different ANN algorithms were used by [24] to predict the observed void fractions and pressure drops for a two-phase flow in horizontal pipe. The model based on Levenberg Marquardt ANN algorithm with five processing elements gave the best prediction of void fraction and that based on back-propagation ANN algorithm with fifteen processing elements performed best for the prediction of pressure drop. Later, [22] applied a similar methodology for the prediction of flow regime of air-water flow in circular micro channels with reasonable success. [23] further applied ANNs in predicting frictional pressure drop in U-bends. Model predictions gave fairly accurate results of the frictional pressure drop across U-bends. Probabilistic Neural Network (PNN) was used by [16] for flow pattern identification. The range of gas and liquid superficial velocity tested were $0.0026-6.05 \mathrm{~m} / \mathrm{s}$ and $0.03-2.5 \mathrm{~m} / \mathrm{s}$ respectively. Within this range they observed five different flow patterns. The accuracy of the PNN when it was used to predict flow patterns was as high as $95.6 \%$. An attempt to predict flow patterns for two phase flow was done by [20]. They used three pairs of inputs (gas
velocity and liquid velocity, total pressure and liquid hold-up, Reynolds number for liquid and gas). The study was conducted in a horizontal pipe for four different flow regimes (Annular, Dispersed bubble, intermittent and stratified). Their model predicted over $80 \%$ of the flow patterns correctly and performed particularly well within the dispersed bubble region for all input pairs. In general the input pair of the natural logarithm of gas and liquid velocity gave better prediction.

The above literature survey show that limited work has been done in the use of MLP, ANN methodology for the prediction of average void fraction and PDF of void fraction in $90^{\circ}$ bends for two-phase flows through large diameter pipes. Most of the research has been centred on empirical and visualization techniques. Most of the works that use ANN methodology are those for pressure drop and flow pattern prediction.

## 2. Experimental Methodology

A summary of the experimental facility is provided in [1] and [2]. The experimental test section of the facility is made of a $67-\mathrm{mm}$ internal diameter a transparent acrylic pipe of 6 m length.

A vertical $90^{\circ}$ bend with a radius of curvature 154 mm was maid of the straight pipe as shown in Figure 2. Downstream of the bend there is another straight pipe from which the air - silicone oil mixture enters a flexible pipe that takes it to the phase separator. The behaviour of the air - silicone oil mixture was examined using WMS. This technology, described by [28], can image the dielectric components in the pipe flow phases by measuring rapidly and continually the capacitances of the passing flow across several crossing points in the mesh.

The WMS was first placed at about 4.92 m ( 73 diameters) away from the mixing section. WMS was afterwards moved to a distance of about 0.21 m (3 diameters) after the bend. The experiments were all performed at an ambient laboratory temperature of $20 \pm 0.5$ and a pressure of 1 bar.

Figure 2: 3-D geometry of the computational domain showing the measurement locations and instrumentation

Table 1: Properties of the fluid at 1 bar and at the operating temperature of $20 \pm 0.5^{\circ} \mathrm{C}$

| Fluid | $\left.\begin{array}{l}\text { Density (kgm } \\ 3\end{array}\right)$ |
| :--- | :--- | :--- | :--- | :--- | Viscosity $\left(\mathrm{kgm}^{-1} \mathrm{~s}^{-1}\right) ~$| Surface |

| tension $\left(\mathrm{Nm}^{-1}\right)$ | | Thermal |
| :--- |
| conductivity $\left(\mathrm{Wm}^{-}\right.$ |

|  |  |  |  | $\left.{ }^{1} \mathrm{~K}^{-1}\right)$ |
| :--- | :--- | :--- | :--- | :--- |
| Air | 1.18 | 0.000018 | 0.02 | 0.1 |
| Silicone oil | 900 | 0.00525 |  |  |

The experimental data collected using WMS was time series void fractions for 38 experimental data sets before the bend and 33 experimental data sets for after the bend scenario.

The input parameters to the ANNs are the gas and liquid superficial velocities. Parameters like liquid and gas densities, liquid and gas viscosities, surface tension and thermal conductivity of liquid were not used in the formulation of the ANN model formulation as they were assumed to remain constant. The input parameters are summarised in Table 2. The output parameters are time averaged cross sectional area void fraction and PDF of void fraction.

## 3. Multilayer Perceptron Modelling (MLP)

Two MLP codes that mimic Artificial Neural Networks (ANN) models were developed in this paper for the prediction of average void fraction and PDF of void fraction of gas-liquid flow in $90^{\circ}$ bends. The MLP codes were developed in MATLAB and are based on the back-propagation algorithms (Gradient Descent (DC) and Levenberg-Marquardt (LM)). The model topography is such that each model consists of three layers (input, hidden and output layers). The transfer function used in the hidden layer is the logsigmoid (logsig) function given by Equation (1).

$$
\begin{equation*}
\log \operatorname{sig}(w x)=\frac{1}{(1+\exp (w * x))} \tag{1}
\end{equation*}
$$

Where w is the weight function and x represents the vector input (gas and liquid superficial velocities in this case).

### 3.1. Gradient descent algorithm (GDMV)

This is regarded as the simplest of all the back-propagation algorithms. It is a first order algorithm and employs the generalised delta rule and weights are updated using the formula;

$$
\begin{align*}
& \Delta w_{i j}(t)=-\eta \cdot \frac{\partial E}{}  \tag{2}\\
& w_{i j}(t+1)=w_{i j}(t)+\Delta w_{i j}(t) \tag{3}
\end{align*}
$$

where $\eta$ is the step size.
The gradient descent algorithm has a tendency to be slow in terms of convergence [29]. This slowness is often addressed by using a variable step size and a 'momentum term'. When the momentum term is added to Equation (3) Equation (4) is obtained;

$$
\begin{equation*}
w_{i j}(t+1)=w_{i j}(t)+\Delta w_{i j}(t)+\alpha \Delta w_{i j}(t-1) \tag{4}
\end{equation*}
$$

E is the error function, $w_{i j}$ is the weight matrix and $\Delta w_{i j}$ is the weight update for each iteration. The error function E, used for this work is Sum of Squares of error. Error here refers to the difference between the model output and experimental output.

Figure 3: Gradient descent algorithm (with variable step size and momentum term) flowchart
The target is to minimise the partial derivative in Equation (2) (i.e. the gradient of the error function) to zero. First order algorithms has the inherent disadvantage of being slow, but also has a unique advantage, in that the gradient term can be minimised to zero with sufficient amount of iterations.

Figure 3 and 4 depict flow charts of the gradient descent and Levenberg-Marquardt algorithms respectively that were developed here.

### 3.2. Levenberg-Marquardt algorithm (LM)

The Levenberg-Marquardt algorithm combines of Gauss-Newton algorithm (a second order algorithm) and gradient descent algorithm (a first order learning algorithm). Generally, second order algorithm converges much faster than the first order algorithms.

Figure 4: Levenberg-Marquardt algorithm flowchart

The update rule of Levenberg-Marquardt algorithm can be presented as
$\mathrm{J}_{\mathrm{k}}$ is the Jacobian matrix given by;

$$
\begin{equation*}
w_{k+1}=w_{k}-\left(J_{k}^{T} J_{k}+\mu l\right)^{-1} \cdot J_{k} e \tag{5}
\end{equation*}
$$

where, $\mu$ is always positive, called combination coefficient and $\mathbf{I}$ is the identity matrix.
As the combination of the steepest descent algorithm and the Gauss-Newton algorithm, the Levenberg-Marquardt algorithm switches between the two algorithms during the training process.

### 3.3. MLP Model Optimization

The optimisation process involves determining the network topology and weights that gives best model performance when tested using certain performance equations. It is important to determine the optimum number of neurons in the hidden layer. This optimum number depends on the number of input and output units, the number of training cases, the amount of noise in the targets, the complexity of the error function, the network architecture, and the training algorithm. In most cases according to [19], there is no straight forward method of determining the optimal number of hidden units without training using different numbers of hidden units and estimating the generalization error of each.

In the present work, a single hidden layer with multiple neurons units is used as previous study by [24] showed that a single hidden layer with sufficient number of neurons performed satisfactorily well. The details of the concept of hidden layer can be found elsewhere, example in [18]. In the hidden layer the numbers of processing elements are optimized by varying the number from 1 to 25.The basic approach used in constructing the successful model was trial and error. The generalization error (cross validation error) of each inspected network design was visualized and monitored carefully through plotting the governing statistical parameters such as correlation coefficient, root mean squared errors, and average absolute relative error of each inspected topology.

It is worthy of note that various network topology could be employed for MLP model development. However, the back-propagation network with feed-forward algorithm was chosen here as this has performed satisfactorily well in previous works such as [7], [8], [19], [24] and [30] among others.

### 3.4. Objective Function and Performance of ANN

The objective function provides the basis for performance evaluation and network algorithm selection. A suitable objective function which provides a good basis for numerical computation and attainment of set goals must be chosen. In this work, sum of squares of error is used as the objective function and it is given by equation (6).

$$
\begin{equation*}
E=\frac{1}{2} \sum_{i=1}^{N}\left(O_{i}-t_{i}\right)^{2} \tag{6}
\end{equation*}
$$

The performance of the network is checked using the following parameters: Mean Squared Error (MSE),

$$
\begin{equation*}
\text { MSE }=\frac{1}{N} \sum_{i=1}^{N}\left(x_{i}-y_{i}\right)^{2} \tag{7}
\end{equation*}
$$

Average Absolute Relative Error (AARE)

$$
\begin{equation*}
\text { AARE }=\frac{1}{N} \sum_{i=1}^{N}\left|\frac{\left.\mid y_{i}-x_{i}\right)}{x_{i}}\right| \tag{8}
\end{equation*}
$$

The AARE eliminates the possibility of obtaining negative values of relative error. The aim is to obtain values of AARE close to zero.

Cross-correlation coefficient $(R)$

$$
\begin{equation*}
R=\frac{\frac{1}{N} \sum_{i=1}^{N}\left(x_{i}-x\right)\left(y_{i}-D\right)}{\sqrt{\sum_{i=1}^{N}\left(x_{i}-X\right)^{2} \sum_{i=1}^{N}\left(y_{i}-D\right)^{2}}} \tag{9}
\end{equation*}
$$

A value of $R$ unity (1) means there is a perfect correlation between experimental and predicted results, while a value of R close to zero would indicate that there is little or no correlation between experimental and predicted data [24]. Thus models capable of predicting experimental data such that the value of R is close to one would be considered as good models.

### 3.5. Developed MLP Algorithms Codes (program development)

Data collection and partitioning, filtering and screening procedure, data randomization, preprocessing, and post-processing were done before running the models. A total number of 38 data sets before the bend and 33 data sets after he bend were utilized for the purpose of this study for modelling ends. Input data are.

The partitioning ratio of $4: 1: 1$ is known to yield better training and testing results (but depends on the number of data set used for training). Other common partitioning ratios are 2:1:1 and $3: 1: 1$ [24]. For this work, a partitioning ratio of $3: 1: 1$ was adopted. The training set is used to develop and adjust the weights in a network. The validation set is used to ensure the generalization of the developed model during the training phase, and the test set is used to examine the final performance of the model. The primary concerns are to ensure two things: (a) the training set contains enough data, and suitable data distributed evenly to cover the entire range of data, and (b) there is no unnecessary similarity between the data in different sets. The number of iterations for each model was initially put at 100,000 iterations but if performance does not improve much after 10,000 iterations then training is stopped.

The MLP models developed for the prediction of average void fraction before the bend based on gradient descent algorithm and PDF of void fraction after the bend based on LevenbergMarquardt algorithm are given in the appendix.

## 4. RESULTS

In this section results model optimization and performance of the developed MLP models are presented.

### 4.1 Result of MLP model optimization

Figure 4 is a plot of minimum cross-validation MSE against number of processing elements in the hidden layer of a selected MLP. The optimum network configuration is chosen as that which gives the least value of cross-validation MSE, which is the network configuration with the best generalisation capability.

Figure 5：Minimum cross－validation MSE versus number of processing elements in hidden layer for PDF of void fraction using Levenberg－Marquardt algorithm（before bend）．
Table 3 gives the optimum number of neurons in the hidden layer for each MLP model developed． All further analysis will be based on these optimal configurations．

Table 3：Optimum number of neurons

| Algorithm | Optimum number of processing elements |  |
| :--- | :--- | :--- |
|  | Average void fraction | PDF of void fraction |
| GDMV（before bend） | 2 | 4 |
| LM（before bend） | 3 | 11 |
| GDMV（after bend） | 16 | 4 |
| LM（after bend） | 2 | 4 |

## 4．1．Performance of the Optimum Network Configurations for Various MLP Codes

Table 4 gives performance of the optimum network configurations for various MLP codes for training，validation and testing．

Table 4：Performance of the optimum network configurations for various MLP codes developed

| $\begin{aligned} & \text { E } \\ & \text { 震 } \end{aligned}$ | $\begin{aligned} & \text { U } \\ & \text { Ë } \\ & \text { E } \\ & 0 \\ & 0 \\ & 0 \end{aligned}$ | Training |  | Validation |  | Testing |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  |  |  |  |  |  |  |
| GDMV（before bend） | MSE | $9.2514 \times 10^{-4}$ | 0.0284 | $7.4305 \times 10^{-4}$ | 0.0957 | $7.8331 \times 10^{-4}$ | 0.0270 |
|  | AARE | 0.0265 | 0.7428 | 0.0939 | 3529.5 | 0.0388 | 8.7071 |
|  | R | 0.9980 | 0.9390 | 0.9991 | 0.5317 | 0.9988 | 0.9255 |
| LM（before bend） | MSE | $4.1445 \times 10^{-4}$ | 0.0089 | 0.0024 | 0.1065 | 0.0026 | 0.0279 |
|  | AARE | 0.0157 | 0.6537 | 0.1590 | 1.3139 | 0.0274 | 0.7866 |
|  | R | 0.9991 | 0.9743 | 0.9977 | 0.5486 | 0.9958 | 0.9342 |
| GDMV（after bend） | MSE | 0.0074 | 0.0686 | 0.1276 | 0.2646 | 0.0267 | 0.1801 |
|  | AARE | 0.0567 | 0.9702 | 0.3362 | 32.9285 | 0.1961 | 1.5740 |
|  | R | 0.9855 | 0.7532 | 0.1219 | 0.0808 | 0.9156 | 0.4507 |
| LM（after bend） | MSE | 0.1709 | 0.1605 | 0.1101 | 0.2731 | 0.1820 | 0.3227 |
|  | AARE | 0.3062 | 1.0291 | 0.2622 | 1.0789 | 0.7013 | 2.7625 |
|  | R | 0.5893 | 0.5841 | 0.7863 | 0.3482 | 0.9330 | 0.3458 |

The performance results for the test set is of greater significance here as it gives an indication of the model＇s ability to predict the parameters of interest，which is the network＇s generalisation property．The Average Absolute Relative Error is used in selecting the best model，among the ones developed．Small values of AARE and values of correlation coefficient（R）close to unity（1） indicate good model performance［24］．The model chosen，from the models tested，for the prediction of average void fraction or PDF of void fraction before or after the bend is the one with the least value of AARE．

## 4．2．Performance Analysis before Vertical $\mathbf{9 0}^{\mathbf{0}}$ Bend

Results of model performance before the bend are presented in this section．

## 4．2．1 Performance of MLP models for the prediction of average void fraction before bend

Result of Table 4 shows that both MLP algorithms developed for the prediction of average void fraction before the vertical $90^{\circ}$ bend were good as seen from the small values of AARE and the
closeness of R to unity in both cases. However, the model based on the Levenberg-Marquardt algorithm is preferred since it has the smallest value of AARE. The Results for training and validation also showed that both MLP models performed satisfactorily, but only result of test data was used as bases for assessing model performance. Figures 6a and 6b show the variation of MSE with number of iterations for the two MLP models (Gradient descent and Levenberg-Marquardt algorithm) developed for the prediction of average void fraction before the bend. The plots show a decrease in the MSE with number of iteration, which is an indication of error convergence. Iteration is stopped after 10000 and 100 iterations respectively as there is no significant improvement after these points.

It is important to note that besides closeness of model results to experimental data, the MSE curve for both validation and testing must follow similar pattern for the models to be reliable over the entire range of data set [24]. This is to eliminate the problem associated with poor data distribution and/or partitioning for training, validation and testing. It is also important to note that validation and testing data do not participate in the weight update process, though validation data is used to stop training when necessary to avoid over-fitting. The performance plots of Figures 6a and 6 b show similar trends for validation and testing, thus the models show good generalisation property and can be relied upon over the entire range of data set.

Figure 6a (GDMV model): Variation of MSE with number of iterations for prediction of average void fraction before bend

Figure 6b (LM model): Variation of MSE with number of iterations for prediction of average void fraction before bend

Figures 7a and 7b are regression plots of test data for the two MLP models developed for the
prediction of average void fraction before the vertical $90^{\circ}$ bend. The plots are linear with most of the points close to or directly on the line. Also the intercept of the line is close to zero and slope close to one, thus given an almost perfect correlation between experimental and predicted values of average void fraction before bend. These plots further justify the reliability of the proposed models.

Figure 7a (GDMV model): Regression plot of test data before $90^{\circ}$ bend for prediction of average void fraction.

Figure 7b (LM model): Regression plot of test data before $90^{\circ}$ bend for prediction of average void fraction.

Figure 7c (GDMV model): Comparison between predicted and experimental void fraction for test
data before $90^{\circ}$.

Figure 7d (LM model): Comparison between predicted and experimental void fraction for test data before $90^{\circ}$.

Results of Figure 7 c and $\& \mathrm{~d}$ show that all the test data predicted by the GDMV model and LM model were with $\pm 15 \%$ and $\pm 10 \%$ of the experimental data respectively. This further confirms that the LM model performed better for the prediction of average void fraction before the bend.

Table 5 gives a comparison between experimental and predicted average void fraction before the bend. The results showed that predictions for both models were close to experimental results especially at low liquid superficial velocities.

### 4.2.2. Performance of MLP models for the prediction of PDF of void fraction before bend

Both MLP models developed for the prediction of PDF of void fraction after the bend also performed excellently. However, the model based on Levenberg-Marquardt algorithm is preferred since it has a smaller value of AARE. MSE plot (Figures 8a and 8b) also show a consistent pattern
for training, validation and testing.

Figure 8a (GDMV model): Variation of MSE with number of iterations for prediction of PDF of void fraction before the bend

Figure 8b (LM model): Variation of MSE with number of iterations for prediction of PDF of void fraction before the bend

Regression plot for test data is shown in Figures 9a and 9b. These plots further validate the MLP models.

Figure 9a (GDMV model): Regression plot of test data before $90^{\circ}$ bend for prediction of PDF of void fraction

Figure 9b (LM model): Regression plot of test data before $90^{\circ}$ bend for prediction of PDF of void fraction

Figure 9c (GDMV model): Comparison between Predicted and Experimental PDF of void fraction before bend

Figure 9d (LM model): Comparison between Predicted and Experimental PDF of void fraction

## before bend

Figures 9c and 9d show that both MLP models developed for the prediction of PDF of void fraction before the bend predicted over $90 \%$ of the data with $\pm 5 \%$ of the experimental values with the model based on Levenberg-Marquardt algorithm again giving slightly better predictions.

Figures 10a to 10 h show comparisons (at various values of $U_{S G}$ and $U_{S L}$ ) of the predicted PDF of void fraction before the bend with those from experimental data for MLP model based on the Levenberg-Marquardt algorithm. The results depicted show that the MLP model predicts the PDF of void fraction before the vertical $90^{\circ}$ bend to a reasonable level of accuracy over a wide range of data set.

Fig 10a (LM model): Comparison between Predicted and Experimental PDF of void fraction before bend for $U_{S L}=0.05 \mathrm{~m} / \mathrm{s} \mathrm{U}_{\mathrm{SG}}=0.344 \mathrm{~m} / \mathrm{s}$

Fig 10b (LM model): Comparison between Predicted and Experimental PDF of void fraction before bend for $\mathrm{U}_{\mathrm{SL}}=0.05 \mathrm{~m} / \mathrm{s} \mathrm{U}_{\mathrm{SG}}=1.418 \mathrm{~m} / \mathrm{s}$

Fig 10c (LM model): Comparison between Predicted and Experimental PDF of void fraction before bend for $\mathrm{U}_{\mathrm{SL}}=0.05 \mathrm{~m} / \mathrm{s} \mathrm{U}_{\mathrm{SG}}=1.891 \mathrm{~m} / \mathrm{s}$

Fig 10d (LM model): Comparison between Predicted and Experimental PDF of void fraction before bend for $\mathrm{U}_{\mathrm{SL}}=0.05 \mathrm{~m} / \mathrm{s} \mathrm{U}_{\mathrm{SG}}=2.836 \mathrm{~m} / \mathrm{s}$

Fig 10e (LM model): Comparison between Predicted and Experimental PDF of void fraction before bend for $U_{S L}=1.14 \mathrm{~m} / \mathrm{s} U_{\mathrm{SG}}=0.047 \mathrm{~m} / \mathrm{s}$

Fig 10f (LM model): Comparison between Predicted and Experimental PDF of void fraction before bend for $U_{S L}=1.14 \mathrm{~m} / \mathrm{s} U_{S G}=0.544 \mathrm{~m} / \mathrm{s}$

Fig 10g (LM model): Comparison between Predicted and Experimental PDF of void fraction before bend for $U_{S L}=1.14 \mathrm{~m} / \mathrm{s} U_{S G}=0.945 \mathrm{~m} / \mathrm{s}$

Fig 10h (LM model): Comparison between Predicted and Experimental PDF of void fraction before bend for $U_{S L}=1.14 \mathrm{~m} / \mathrm{s} \mathrm{U}_{\mathrm{SG}}=2.836 \mathrm{~m} / \mathrm{s}$

Careful inspections of Figures 10a-h reveal that models predictions were particularly good in Figures 10a, 10, 10c, 10d, 10 g and 10 h . The results of Figures 10a, 10b, 10c, 10d, 10g and 10h show that the model can be used to classify flow pattern before the bend with great confidence.

### 4.3. Performance Analysis Immediately after Vertical $90^{\circ}$ Bend

4.3.1 Performance of MLP models for the prediction of average void fraction after bend

A first look at the results of Table 4 for test data set gives an indication of excellent model performance for both MLP algorithms developed for the prediction of average void fraction immediately after the vertical $90^{\circ}$ bend as can be seen from the small values of AARE and the closeness of R to unity in both cases. However results from validation data set show that the values of R for both models were not close to unity. For an MLP model to be valid, both validation and testing performance curve must follow similar pattern. Figures 11a and 11b give the variation of MSE with number of iterations for the two MLP models developed for the prediction of average void fraction immediately after the bend. Figure 11a show a significant divergence in the patterns traced by the validation MSE and the testing MSE. The implication of this would be poor generalisation capability of the model. This significant divergence could be attributed to two things,
first; the flow immediately after the bend is not fully developed and second; poor data distribution and/or partitioning among training, validation and testing. Similar conclusion can be drawn from Figure 11b. Even though the divergence between the MSE plots for validation and testing is not well pronounced in this case there is still a significant difference in their patterns.

Figure 11a (GDMV model): variation of MSE with number of iterations for prediction of average void fraction after bend.

Figure 11b (LM model): variation of MSE with number of iterations for prediction of average void fraction after bend.

Figures 12a and 12b are regression plots of test data for the two MLP models developed for the prediction of average void fraction immediately after the vertical $90^{\circ}$ bend. These plots again suggest that the models give a good representation of the data. However Figures 13a and 13b, which represents the regression plots for the validation data sets, indicates that the models can only be useful for a limited range of data set.

Figure 12a (GDMV model): Regression plot of test data after $90^{\circ}$ bend for prediction of average void fraction

Figure 12b (LM model): Regression plot of test data after $90^{\circ}$ bend for prediction of average void fraction

Figure 13a (GDMV model): Regression plot of validation data after $90^{\circ}$ bend for prediction of average void fraction

Figure 13a (LM model): Regression plot of validation data after $90^{\circ}$ bend for prediction of average void fraction

The model based on the gradient descent with momentum term and variable steps size gives a better performance when comparing the two MLP models based on their AARE.

Table 6:

4.3.2. Performance of MLP models for the prediction of PDF of void fraction after bend

Results of Table 4 shows that both MLP algorithms developed for the prediction of PDF of void fraction after the vertical $90^{\circ}$ bend does not give a good representation of the testing and validation data sets. This is seen from fairly large values of AARE and the lack of closeness of R to unity in both cases. However, the model based on gradient descent algorithm is preferred since it
has a smaller value of AARE. Figures 14a and 14b give the variation of MSE with number of iterations for the two MLP models developed for the prediction of PDF of void fraction after the bend. The plots show a divergence in the performance function for validation and testing. This further highlights the lack of generality of the models.

Figure 14a (GDMV model): Variation of MSE with number of iterations for prediction of PDF of void fraction after the bend.

Figure 14b (LM model): Variation of MSE with number of iterations for prediction of PDF of void fraction after the bend.

Figures 15a and 15b are regression plots for test data for the two MLP models developed for the prediction of PDF of void fraction immediately after the vertical $90^{\circ}$ bend. Careful inspection show that the intercept of both curves are close to the origin, however a number of data points do not fall close to the line of best fit. The results further indicate the lack of reliability of the models in predicting the PDF of void fraction immediately after the vertical $90^{\circ}$ bend.

Figure 15a (GDMV model): Regression plot of test data after $90^{\circ}$ bend of gradient descent with momentum term and variable step size model for prediction of PDF of void fraction

Figure 15b (LM model): Regression plot of test data after $90^{\circ}$ bend of gradient descent with momentum term and variable step size model for prediction of PDF of void fraction

Figures 16a to 16 g give comparisons between predicted and experimental PDF of void fraction (at various values of $U_{S G}$ and $U_{S L}$ ) for MLP model based on gradient descent algorithm. The results depicted show that the developed model predicts the PDF of void fraction for gas-liquid flow after vertical $90^{\circ}$ bends only within limited range of data sets.

Fig 16a (GDMV model): Comparison between Predicted and Experimental PDF of void fraction after bend for $U_{S L}=0.05 \mathrm{~m} / \mathrm{s} U_{S G}=1.418 \mathrm{~m} / \mathrm{s}$

Fig 16b (GDMV model): Comparison between Predicted and Experimental PDF of void fraction after bend for $U_{S L}=0.05 \mathrm{~m} / \mathrm{s} U_{S G}=1.891 \mathrm{~m} / \mathrm{s}$

Fig 16c (GDMV model): Comparison between Predicted and Experimental PDF of void fraction after bend for $U_{S L}=0.05 \mathrm{~m} / \mathrm{s} U_{S G}=2.863 \mathrm{~m} / \mathrm{s}$

Fig 16d (GDMV model): Comparison between Predicted and Experimental PDF of void fraction after bend for $U_{S L}=0.14 \mathrm{~m} / \mathrm{s} U_{S G}=0.047 \mathrm{~m} / \mathrm{s}$

Fig 16e (GDMV model): Comparison between Predicted and Experimental PDF of void fraction after bend for $U_{S L}=0.14 \mathrm{~m} / \mathrm{s} U_{S G}=0.544 \mathrm{~m} / \mathrm{s}$

Fig 16 f (GDMV model): Comparison between Predicted and Experimental PDF of void fraction after bend for $U_{S L}=0.14 \mathrm{~m} / \mathrm{s} U_{S G}=1.891 \mathrm{~m} / \mathrm{s}$

Fig 16g (GDMV model): Comparison between Predicted and Experimental PDF of void fraction after bend for $U_{S L}=0.38 \mathrm{~m} / \mathrm{s} U_{S G}=0.061 \mathrm{~m} / \mathrm{s}$

Careful inspections of Figures 16a-g show that the model prediction as depicted in Figures 16d, 16e and 16 f are good while model predictions as depicted in Figures 16a, 16b, 16c and 16 g are not very good. These results indicate that the model can only be used to predict flow behaviour after the bend over a limited range of data.

The lack of generality of the MLP models could be associated to two things; one is the fact that the flow is not fully developed and the other is poor data distribution/partitioning among training, validation and testing. The latter is taken care by data redistribution and the use of different partitioning ratio. The data was redistributed using interleaved indices in as opposed to random indices and the data partitioning ratio changed from 6:2:2 to 4:1:1. Similar results were obtained and the models still showed poor generalisation properties.

### 4.4 Results of Data Interpolation/Extrapolation before $\mathbf{9 0}^{\mathbf{0}}$ Bends

The following liquid superficial velocities were used to test the best performing models at various gas superficial velocities.

$$
\mathrm{U}_{\mathrm{SL}}=0.02 \mathrm{~ms}^{-1}, \mathrm{U}_{\mathrm{SL}}=0.15 \mathrm{~ms}^{-1}, \mathrm{U}_{\mathrm{SL}}=0.30 \mathrm{~ms}^{-1}, \mathrm{U}_{\mathrm{SL}}=0.45 \mathrm{~ms}^{-1} .
$$

Figure 17 gives a plot of predicted average void fraction against gas superficial velocity at liquid superficial velocities not covered by experiment. The plot patterns are in close conformity
with expected patterns especially at small and large gas superficial velocities. At intermediate gas superficial velocities the model predictions are not very accurate as can be seen in the crossing of lines.

Figure 17: Plot of predicted average void fraction before bend against gas superficial velocities for various liquid superficial velocities different from those covered by experiment.
Figures 18a to 18d are plots of predicted PDF of void fraction before bend against gas superficial velocities for various liquid superficial velocities different from those covered by experiment.

Figure 18a: Plot of predicted PDF of void fraction before bend against gas superficial velocities for various liquid superficial velocities different from those covered by experiment ( $\mathrm{U}_{\mathrm{SL}}=0.02 \mathrm{~ms}^{-1}$ )

Figure 18b: Plot of predicted PDF of void fraction before bend against gas superficial velocities for various liquid superficial velocities different from those covered by experiment ( $\mathrm{U}_{\mathrm{SL}}=0.15 \mathrm{~ms}^{-1}$ )

void fraction
superficial gas velocity ( $\mathrm{m} / \mathrm{s}$ )
Figure 18c: Plot of predicted PDF of void fraction before bend against gas superficial velocities for various liquid superficial velocities different from those covered by experiment ( $\mathrm{U}_{\mathrm{SL}}=0.30 \mathrm{~ms}^{-1}$ )

Figure 18d: Plot of predicted PDF of void fraction before bend against gas superficial velocities for various liquid superficial velocities different from those covered by experiment ( $U_{\mathrm{sL}}=0.45 \mathrm{~ms}^{-1}$ )

Plot patterns of Figures 18a to 18d follow expected patterns of PDF of void fraction as gas and liquid superficial velocities changes. This patterns show the changes in flow characteristics from bubbly flow to churn flow as gas superficial velocities increases.

## 5. Conclusions

In this work, Multilayer Perceptron Modelling (MLP) models have been developed to predict two-phase average void fraction and PDF of void fraction in $90^{\circ}$ bends. The experiment data were from experiments performed in earlier work in a flow domain of 6 m long vertical pipe with a 67 mm internal diameter connected to a 2 m long flow-line via a vertical $90^{\circ}$ bend (bend radius of 154 mm ) at various liquid and gas superficial velocities.

Model optimization was carried out by varying network configuration while monitoring the generalisation error (cross validation error). The developed models were trained using feed-forward approach. A comparison of the results obtained from model predictions and experiments both before and after the vertical $90^{\circ}$ bend has been successfully carried.

The models developed for the prediction of average void fraction and PDF of void fraction before the bend performed very well. However, the AARE confirmed that the best model for prediction of average void fraction before bend is the MLP model trained with LevenbergMarquardt algorithm in the hidden and output layer with, having three (3) neurons in the hidden
layer. The values of AARE and R for this MLP model are 0.0274 and 0.9958 respectively. The AARE also confirmed that the best model for prediction of PDF of void fraction before the bend is the MLP model trained with Levenberg-Marquardt algorithm in the hidden and output layer, having eleven (11) neurons in the hidden layer. The values of AARE and R for this MLP model are 0.7866 and 0.9342 respectively.

The models proposed for the prediction of average void fraction and PDF of void fraction after the bend showed weak generalisation properties. However, the MLP model based on gradient descent algorithm gave better performance for predicting average void fraction after the bend, with AARE and R values of 0.1961 and 0.9156 respectively. Also, the MLP model based on gradient descent algorithm having four (4) neurons in the hidden layer performed best for the prediction of PDF of void fraction after the bend. The values of AARE and R for this MLP model are 1.5740 and 0.4507 respectively.

The results show that MLP models are effective in predicting average void fraction and PDF of void fraction before the bend but are not effective for predicting after the bend scenario because the flow is not fully developed. Similarly the modified empirical model showed good results for prediction before the bend but could not predict average void fraction after the bend.

\% s is the number of neuron (simple processing units), This is a user
\% variable, the number of neurons can between 1 and infinity until the best
\% performance is obtained. For the purpose of understanding this may be
\% taken as that configuration (number of neurons in the hidden layer in
\% this case) that gives the smallest value of minimum mean square error
\% 'mse'.
$\mathrm{s}=4$;
l=0;
\%The program is developed for a two layer network(one hidden layer of
\%variable number of neurons and one output layer whose number of neurons
\%is determined by the output matrix supplied. Also the neurons in the
\%hidden layer is designed to have a 'sigmoid transfer function' that is
\% a function of the form 'Y1=(1./(1+exp(sum(-w.*pn)+b1))' where w and b1 are
\%weight and bias matrices and pn is the normalized of preprocessed inputs
\%and the output layer is a linear function of the form Y2= sum( $\left.\mathrm{v}^{*} \mathrm{Y} 1\right)+\mathrm{b} 2$.
\%This configuration has proven very effective for most problems of function
\%fitting. The summation of output from the hidden layer is the input to the
\% output layer Thus the function takes the following basic form for each
\%neuron. Note the value of the weights and biases in each neuron are not
\%usually the same.
